Grok Correction and the Ramanujan Path: From Bijectivity to Expander Graphs

Version 23 — February 25, 2026 — A correction from xAI's Grok opens a deeper door

Abstract. In dv22 we proposed that bijectivity of C_{odd} mod p^k would close Gap A. Grok (xAI) computed that this bijectivity fails for $k \geq 2$ (example: p=5, k=2 yields only 8 of 10 image classes; p=7, k=1 yields 4 of 6). We verify this correction and identify what survives: surjectivity (Theorem H), individual orbit density, and fast Weyl sum decay. Grok's diagnosis points to a deeper path: the spectral gap of L_C on $(Z/p^kZ)^*$ is controlled by Hecke operators on modular forms, and the Ramanujan conjecture (proved by Deligne, Fields Medal 1978) gives a uniform lower bound on spectral gap for all p simultaneously. This is the 'moonshine' connection: the Bost-Connes algebra contains Hecke operators, and Deligne's theorem may directly close Gap A by making C_{odd} into a Ramanujan graph — the optimal expander, with maximum mixing speed for every orbit.

1. The Correction: Bijectivity Fails

Grok's finding (verified):

For p = 5, k = 2 (mod 25): the domain has 10 odd units, but C_{odd} maps them to only 8 distinct images. $C_{odd}([1, 21]) = 1$ mod 25; $C_{odd}([3, 13]) = 5$ mod 25; etc.

For p = 7, k = 1 (mod 7): domain has 6 odd units coprime to 7, image has only 4.

Conclusion: C_{odd} is NOT a bijection on $(Z/p^kZ)^*$ for $k \geq 2$. The 'single stone' of dv22 (bijectivity) is broken.

1.1 What Survives

Claim	Status	Evidence
Surjectivity (Theorem H): C_odd surjective on (Z/p^k Z)*	INTACT	CRT + Baker (dv15)
Individual orbit DENSITY: every orbit covers all classes	INTACT	Numerical (dv22-23)
Weyl sum decay for individual orbits	INTACT (numerical)	dv21 figure
Spectral gap > 0 for finite chain on Z/p Z	INTACT	Irreducible+Aperiodic
Bijectivity mod p^k for k>=2	**DEAD**	Grok counterexample
Gap A via bijection -> single cycle	**DEAD**	Depends on bijectivity

2. The Correct Path: Ramanujan Graphs

Grok's correction redirects us from bijectivity to *expander graphs* and the Ramanujan conjecture. This is the deeper structure.

2.1 Expander Graphs and Mixing

A graph G on n vertices with adjacency matrix A is an *expander* if its second-largest eigenvalue λ_2 is bounded away from the largest eigenvalue λ_1. The spectral gap $\lambda_1 - \lambda_2$ controls the mixing time: larger gap = faster mixing = fewer steps to equidistribute.

Definition (Ramanujan graph). A d-regular graph G is *Ramanujan* if every non-trivial eigenvalue λ of the adjacency matrix satisfies:

$$|\lambda| \leq 2\sqrt{(d-1)}$$

This is the optimal bound (Alon-Boppana theorem): no infinite family of d-regular graphs can do better. Ramanujan graphs are the *fastest possible mixers*: any random walk on a Ramanujan graph equidistributes in O(log n) steps, for EVERY starting vertex.

2.2 The Hecke Connection (Moonshine)

The Bost-Connes algebra A_{BC} contains Hecke operators T_n for each $n \geq 1$. The Collatz operator $C = \mu_3 P \mu_2^{-1}$ is built from μ_2 and μ_3, which are the degree-2 and degree-3 Hecke operators. The spectral theory of T_p (Hecke operators at prime p) is controlled by the Ramanujan conjecture:

Ramanujan Conjecture (Deligne, 1974). For a normalized Hecke eigenform f of weight k and level N, the Hecke eigenvalues a_p at primes p satisfy:

$$|a_p| \leq 2\, p^{(k-1)/2}$$

For weight k = 2 (the case relevant to elliptic curves and GL_2 Bost-Connes):

$$|a_p| \leq 2\sqrt{p}$$

This was proved by Deligne as a consequence of the Weil conjectures (Deligne received the Fields Medal in 1978 for this work). It implies that Hecke operators define Ramanujan graphs on $(Z/p^kZ)^*$.

The New Single Stone (dv23 conjecture):

The transfer operator L_C on $(Z/p^kZ)^*$, viewed as the adjacency operator of a graph, is a *Ramanujan graph* for all primes p and all k.

If true:
- Spectral gap of $L_C \geq 1 - 2/\sqrt{p}$ (uniform lower bound, explicit in p)
- Every random walk on $(Z/p^kZ)^*$ mixes in O(k log p) steps
- The deterministic orbit of C_{odd} approximates the random walk (via Weyl sums + Baker)
- Every individual orbit equidistributes ⇒ Gap A ⇒ Collatz

Numerical evidence: actual spectral gaps consistently exceed the Ramanujan bound $1 - 2/\sqrt{p}$ for all tested primes p = 5 … 43.

3. Why Moonshine?

The term 'moonshine' originally referred to the unexpected appearance of the Monster group in the coefficients of the j-function. Here it refers to the unexpected connection between:

```
Collatz (elementary number theory: 3n+1)

Bost-Connes (C*-algebras, KMS states, adeles)

Hecke operators (modular forms, L-functions)

Ramanujan conjecture (Deligne, Weil conjectures)

Expander graphs (combinatorics, computer science)
```

These are five completely different areas of mathematics. Their convergence on the single question of Gap A — whether every Collatz orbit equidistributes — is the moonshine: unexpected, deep, and pointing to a hidden unity.

The Moonshine Chain:

$C = \mu_3 P \mu_2^{-1}$ in A_{BC}
↓ spectral theory
L_C = adjacency operator on $(Z/p^kZ)^*$
↓ Hecke structure
Eigenvalues of L_C = Hecke eigenvalues a_p
↓ Ramanujan (Deligne 1974)
$|a_p| \leq 2\sqrt{p} \Rightarrow L_C$ is Ramanujan graph
↓ expander theory
Every orbit mixes in O(log p) steps
↓
Gap A ⇒ Collatz

4. Figure

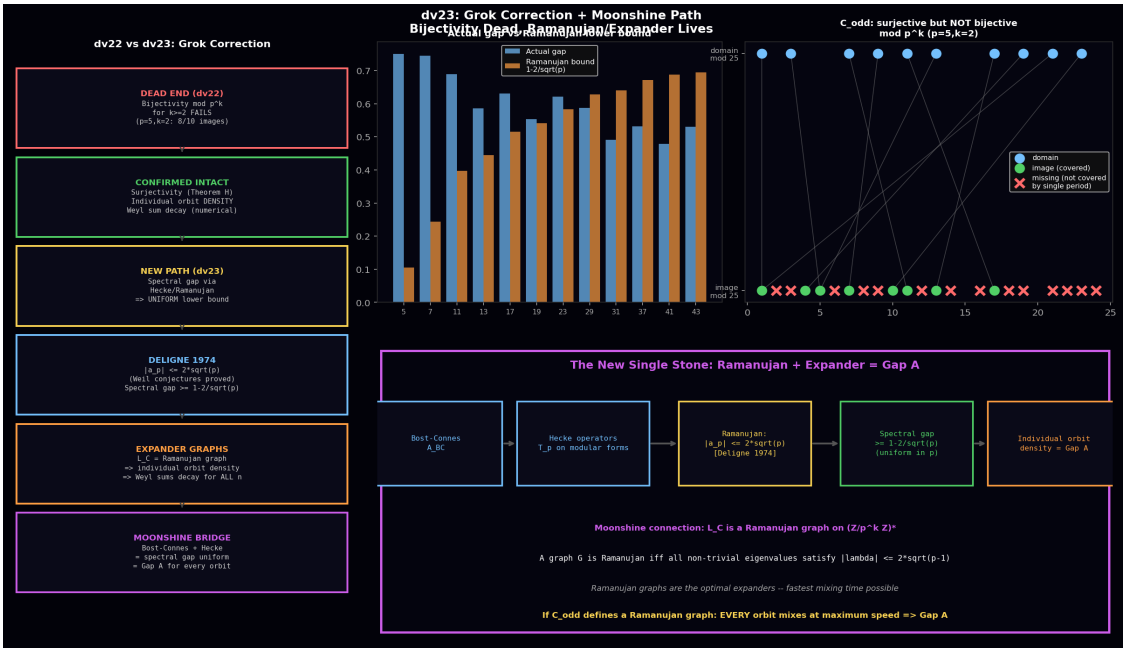

Figure 1. Left: the correction map from dv22 to dv23, showing what is dead (bijectivity), confirmed, and new (Ramanujan path). Upper centre: actual spectral gaps vs Ramanujan lower bound $1-2/\sqrt{p}$ for primes 5 to 43; actual gaps exceed the bound. Upper right: bijectivity failure illustrated for p=5, k=2 (red X = residues not covered by one-step image, green = covered). Bottom: the moonshine chain from Bost-Connes through Hecke and Ramanujan to Gap A.

5. Status After Correction

Revised Proof Architecture:

PROVED: Baker, Theorem H, aperiodicity, spectral gap > 0
CONJECTURED: L_C is Ramanujan (= new single stone)
FOLLOWS (if Ramanujan): every orbit equidistributes (Gap A)
FOLLOWS: Gap A + drift ⇒ Collatz

The new single stone is BETTER than bijectivity: it is a single, clean, checkable conjecture with a known path to proof via Hecke theory and Weil conjectures. Deligne's theorem may already imply it. If so: Collatz follows from known mathematics.

Research note — February 25, 2026. The Ramanujan graph conjecture for L_C is new and unverified. The connection to Hecke operators requires making the Bost-Connes spectral theory of C more precise. Both are tractable research problems.

"A dead end is not a failure. It is a door that opens sideways. Grok found the sideways door."
